Abstract—The peristaltic motion of a Carreau fluid in an asymmetric channel with partial slip is studied under long wave length and low Reynolds number assumptions which are also used to solve the problem. Applying perturbation technique, the expressions for stream function, axial velocity, axial pressure gradient, pressure rise, shear stress and frictional forces have been obtained. The effects of various emerging parameters on the flow characteristics are shown and discussed with the help of graphs. The pumping is examined for different wave forms. The results of the current paper reveal that the size of the trapping bulus increases by Carreau fluid (n=0.398) to Newtonian fluid (n=1).

Keywords—peristaltic transport, asymmetric channel, Weissenberg number, partial slip, shear stress, trapping, different wave forms.

I. INTRODUCTION

The study of peristaltic transport in fluid mechanics has been carried out by many researchers to look for its implication in the biological sciences in general and in biomechanics in particular. The peristaltic flow occurs due to the contraction and expansion of a progressive wave propagating along the length of a distensible tube containing fluid. Peristaltic wave causing transportation of the fluid through muscular tube is indeed an important biological mechanism responsible for various physiological functions of many organs of the human body. Such mechanism may be involved in urine transport from kidney to bladder through the ureter, swallowing foods through the esophagus, the transport of spermatozoa in the cervical canal, the movement of chyme in small intestines and in the transport of bile. Such a wide occurrence of peristaltic motion should not be surprising at all since it results physiologically from neuro-muscular properties of any tubular smooth muscle.

Most of the previous works in the literature deals with the peristaltic flow in a symmetric channel or tube. Due attention has not been given to the peristaltic mechanism in an asymmetric channel. Recently, physiologists observed that myometrial contractions may occur in both symmetric and asymmetric directions. Eytan and Elad [1] have presented a mathematical model of wall induced peristaltic fluid flow in a two-dimensional channel with wave trains having a phase difference moving independently on the upper and lower walls to stimulate intra-uterine fluid motion in a sagittal cross-section of the uterus. In another paper, Eytan et al. [2] reported that the width of the sagittal cross-section of the uterine cavity increases towards the fundus and the cavity is not fully occluded during the contractions. Mishra and Rao [3] discussed the peristaltic motion of viscous fluid in a two-dimensional asymmetric channel under long wavelength assumption. Rao and Mishra [4] also analyzed the curvature effects on peristaltic transport in an asymmetric channel. Hayat et al [5] studied peristaltic flow of a micropolar fluid in a channel with different wave forms. Vajravelu et al. [6] investigated the peristaltic transport of a Casson fluid in contact with a Newtonian fluid in a circular tube with permeable wall. Ali and Hayat [7] made a detailed study as the peristaltic motion of a Carreau fluid in an asymmetric channel with impermeable walls. Vajravelu et al [8] studied peristaltic transport of a Williamson fluid in asymmetric channels with permeable walls. Since many biological systems such as blood vessels contain a tissue layer it will be interesting to study peristaltic transport of a biofluid through asymmetric channel with partial slip. Prasanna et al [9] examined the peristaltic transport of non-Newtonian fluid in a diverging tube with different wave forms as the peristaltic wave form in living organisms is not known. This method has already been used for the solutions of several other problems [12–15].

The main objective of the present investigation is to put forward the analysis of peristaltic flow of a Carreau fluid in an asymmetric channel. The Carreau fluid model is a four parameter model and has useful properties of a truncated power law model that does not have a discontinuous first derivative. The relevant equations for the fluid under consideration have been first modeled and then solved. The assumption for the solution is that wavelength of the peristaltic wave is long. A regular perturbation technique is employed to solve the present problem and solutions are expanded in a power of small Weissenberg number. The analysis is made for the stream function, axial pressure gradient and pressure drop over a wavelength. The influence of emerging parameters is shown on pumping, pressure gradient and trapping.

II. MATHEMATICAL FORMULATION

Let us consider the peristaltic transport of an incompressible Carreau fluid in a two-dimensional channel of width \(d_1 + d_2\) (Fig. 1). The flow is generated by sinusoidal wave trains propagating with constant speed c along the permeable walls of the channel. The geometry of the wall surfaces is defined as
Fig. 1: Schematic diagram of a two-dimensional asymmetric channel

\[ h_1(\bar{x}, \bar{y}) = \bar{a}_1 + \bar{a}_1 \cos \left( \frac{2\pi}{\lambda} (\bar{x} - ct) \right) \]  
upper wall,

\[ h_2(\bar{x}, \bar{y}) = -\bar{a}_2 - \bar{a}_2 \cos \left( \frac{2\pi}{\lambda} (\bar{x} - ct) + \phi \right) \]  
lower wall.

in which \( \bar{a}_1 \) and \( \bar{a}_2 \) are the amplitudes of the waves, \( \lambda \) is the wave length, \( c \) is the wave speed, \( \phi \) (\( 0 \leq \phi \leq \pi \)) is the phase difference, \( \bar{x} \) and \( \bar{y} \) are the rectangular coordinates with \( \bar{x} \) measured along the axis of the channel and \( \bar{y} \) is perpendicular to \( \bar{x} \). Let \((\vec{u}, \vec{v})\) be the velocity components in fixed frame of reference \((\bar{x}, \bar{y})\). It should be noted that \( \phi = 0 \) corresponding to symmetric channel with waves out of phase and for \( \phi = \pi \) the waves are in phase. Furthermore, \( \bar{a}_1, \bar{a}_2, \bar{d}_1, \bar{d}_2, \) and \( \phi \) satisfy the condition

\[ \bar{a}_1^2 + \bar{a}_2^2 + 2\bar{a}_1\bar{a}_2 \cos \phi \leq (\bar{d}_1 + \bar{d}_2)^2. \]  

III. EQUATIONS OF MOTION

The constitutive equation for a Carreau fluid is (Ref. [7])

\[ \tau = \left[ \eta_0 + \left( \eta_0 - \eta_n \right) \left( \frac{1}{1 + \left( \Gamma \eta' \right)^2} \right)^{n-1} \right] \gamma', \]  

where \( \tau \) is the extra stress tensor, \( \eta_0 \) is the infinite shear rate viscosity, \( \eta_n \) is the zero shear-rate viscosity, \( \tau \) is the time constant, \( n \) is the dimensionless power law index and \( \gamma' \) is defined as

\[ \gamma' = \left( \frac{1}{2} \sum_g \sum_y \gamma_{y} \gamma_{y} \right)^{1/2}. \]  

here \( \eta \) is the second invariant of strain-rate tensor. We consider in the constitutive Eq. (4) the case for which \( \eta_n = 0 \), and so we can write

\[ \tau = -\eta_0 \left[ 1 + \left( \Gamma \eta' \right)^2 \right]^{n-1} \gamma'. \]  

The above model reduces to Newtonian Model for \( n=1 \) or \( \Gamma=0 \).

The flow is unsteady in the laboratory frame \((\bar{x}, \bar{y})\). However, if observed in a moving coordinate system with the wave speed \( c \) (wave frame) \((\bar{x}, \bar{y})\) it can be treated as steady. The coordinates and velocities in the two frames are

\[ \bar{x} = \bar{x} - ct, \quad \bar{y} = \bar{y}, \quad u(\bar{x}, \bar{y}) = \bar{U} - c, \quad v(\bar{x}, \bar{y}) = \bar{V}. \]  

where \( \bar{U} \) and \( \bar{V} \) indicate the velocity components in the wave frame. The equations the following of a Carreau fluid are given by

\[ \frac{\partial \bar{u}}{\partial \bar{x}} = 0, \]  

\[ \rho \left( \frac{\partial \bar{u}}{\partial \bar{x}} + \bar{v} \frac{\partial \bar{u}}{\partial \bar{y}} \right) = -\frac{\partial \bar{p}}{\partial \bar{x}} - \frac{\partial \tau_{xx}}{\partial \bar{x}} - \frac{\partial \tau_{xy}}{\partial \bar{y}}, \]  

\[ \rho \left( \frac{\partial \bar{v}}{\partial \bar{x}} + \bar{v} \frac{\partial \bar{v}}{\partial \bar{y}} \right) = -\frac{\partial \bar{p}}{\partial \bar{y}} - \frac{\partial \tau_{yx}}{\partial \bar{x}} - \frac{\partial \tau_{yy}}{\partial \bar{y}}. \]  

The following non-dimension quantities are also defined
\[
\begin{align*}
\mathbf{x} &= \frac{x}{\lambda}, \quad y = \frac{y}{\lambda}, \quad u = \frac{u}{c}, \quad v = \frac{v}{c}, \quad t = \frac{t}{\tau}, \quad h_i = \frac{h_i}{d_i}, \quad \gamma = \frac{\gamma}{d_i}.
\end{align*}
\]

\[
\begin{align*}
\frac{\partial h_i}{\partial t} - \frac{\partial \gamma}{\partial x} &= \frac{\partial}{\partial x} \left( \frac{1}{\lambda} \left[ \frac{1}{\lambda} \left( \frac{n-1}{2} \right) We \right]^2 \frac{\partial \gamma}{\partial x} \right) + \frac{\partial^2 \gamma}{\partial y^2} + \frac{\partial}{\partial y} \left( \frac{1}{\lambda} \left( \frac{n-1}{2} \right) We \right)^2 \frac{\partial \gamma}{\partial y}.
\end{align*}
\]

and \( \delta, \ Re \) and \( \text{We} \) are the wave, Reynolds and Weisssenberg numbers, respectively. Under the assumptions of long wavelength and low Reynolds number, Eqs. (13) - (14) after using Eq. (16) become

\[
\frac{\partial p}{\partial x} = \frac{\partial}{\partial y} \left[ 1 + \frac{1}{\lambda} \left( \frac{n-1}{2} \right) We \right] \left( \frac{\partial^2 p}{\partial y^2} \right) + \frac{\partial^2 p}{\partial y^2} = 0.
\]

On eliminating the pressure \( p \) from Eqs. (19) - (20), we finally get

\[
\frac{\partial^2}{\partial y^2} \left[ 1 + \frac{1}{\lambda} \left( \frac{n-1}{2} \right) We \right] \left( \frac{\partial^2 \gamma}{\partial y^2} \right) + \frac{\partial^2 \gamma}{\partial y^2} = 0.
\]

IV. RATE OF VOLUME FLOW AND BOUNDARY CONDITIONS

In laboratory frame, the dimensional volume flow rate is

\[
Q = \int_{\mathcal{X}} \mathcal{G}(x, y, \tau, \gamma) d\mathcal{F}.
\]

in which \( h_i \) and \( h_i \) are functions of \( \mathcal{X} \) and \( \mathcal{F} \). the above expression in the wave frame becomes

\[
q = \int_{\mathcal{H}(\tau)} \mathcal{G}(\mathcal{X}, \gamma) df,
\]

where \( \mathcal{P} \) and \( \mathcal{P} \) are only functions of \( \mathcal{X} \). from Eqs. (7), (22) and (23) we can write

\[
Q = q + c\tilde{h}(\mathcal{X}) - c\tilde{h}(\mathcal{X}).
\]

The time- averaged flow over a period \( T \) at a fixed position \( \mathcal{X} \) is given as

\[
\bar{Q} = \frac{1}{T_0} \int_0^T Q dt.
\]

Where
\[ \bar{Q} = \frac{\theta}{cd_i}, \quad q = \frac{F}{cd_i}, \]  

(26) \[ F = \int_{h_{0}(x)}^{h_{1}(x)} \frac{\partial \psi}{\partial y} \, dy = \psi(h_{1}(x)) - \psi(h_{0}(x)) \]  

(27)

Here, \( h_{1}(x) \) and \( h_{0}(x) \) represent the dimensionless form of the surfaces of the peristaltic walls

\[ h_{1}(x) = 1 + a \cos 2\pi x, \]  

(28) \[ h_{0}(x) = -d - b \cos(2\pi x + \phi). \]  

(29)

On substituting (24) into (25) and performing the integration, we obtain

\[ \theta = F + cd_{1} + cd_{2}. \]  

(30)

Inserting Eq. (26) into Eq. (30), yields

\[ \bar{Q} = q + 1 + d. \]  

(31)

In the wave frame, the boundary conditions in terms of streams function \( \psi \) are (Ref. [10])

\[ \psi = \frac{q}{2} \text{ at } y = h_{1}(x), \]  

(32) \[ \psi = -\frac{q}{2} \text{ at } y = h_{0}(x), \]  

(33) \[ \frac{\partial \psi}{\partial y} + \beta \frac{\partial^2 \psi}{\partial y^2} = -1 \text{ at } y = h_{1}(x), \]  

(34) \[ \frac{\partial \psi}{\partial y} - \beta \frac{\partial^2 \psi}{\partial y^2} = -1 \text{ at } y = h_{0}(x). \]  

(35)

V. PERTURBATION SOLUTION

For perturbation solution, we expand \( \psi \), \( q \) and \( p \) as

\[ \psi = \psi_{0} + We^{2} \psi_{1} + O(We^{4}), \]  

(36) \[ q = q_{0} + We^{2} q_{1} + O(We^{4}), \]  

(37) \[ p = p_{0} + We^{2} p_{1} + O(We^{4}). \]  

(38)

System of order \( We^{0} \):

\[ \frac{\partial^2 \psi_{0}}{\partial y^2} = 0. \]  

(39)

\[ \frac{\partial p_{0}}{\partial x} = \frac{\partial \psi_{0}}{\partial y}, \]  

(40) \[ \psi_{0} = \frac{q_{0}}{2} \text{ at } y = h_{1}(x), \]  

(41) \[ \psi_{0} = -\frac{q_{0}}{2} \text{ at } y = h_{0}(x), \]  

(42) \[ \frac{\partial \psi_{0}}{\partial y} + \beta \frac{\partial^2 \psi_{0}}{\partial y^2} = -1 \text{ at } y = h_{1}(x), \]  

(43) \[ \frac{\partial \psi_{0}}{\partial y} - \beta \frac{\partial^2 \psi_{0}}{\partial y^2} = -1 \text{ at } y = h_{0}(x). \]  

(44)

System of order \( We^{2} \):

\[ \text{(replace } \psi \text{ by } \psi_{0}) \frac{\partial^2 \psi_{0}}{\partial y^2} + \frac{(n-1)}{2} \frac{\partial \psi_{0}}{\partial y} \left( \frac{\partial^2 \psi_{0}}{\partial y^2} \right) = 0. \]  

(45) \[ \frac{\partial p_{0}}{\partial y} = \frac{\partial \psi_{0}}{\partial y} + \frac{(n-1)}{2} \frac{\partial \psi_{0}}{\partial y} \left( \frac{\partial^2 \psi_{0}}{\partial y^2} \right), \]  

(46) \[ \psi_{1} = \frac{q_{1}}{2} \text{ at } y = h_{1}(x), \]  

(47)
\[ \psi_i = -\frac{q_i}{2} \text{ at } y = h_i(x), \]  
\[ \frac{\partial \psi_i}{\partial y} + \beta \frac{\partial^2 \psi_i}{\partial y^2} = 0 \text{ at } y = h_i(x), \]  
\[ \frac{\partial \psi_i}{\partial y} - \beta \frac{\partial^2 \psi_i}{\partial y^2} = 0 \text{ at } y = h_2(x) \]  

A. Solution for system of order \(0\):

Solving Eq. (39) and then using the boundary conditions given in (41) - (44) we have
\[ \psi_i = A_i \frac{y^3}{3!} + A_i \frac{y^2}{2!} + A_i y + A_i \]  
where
\[ A_i = -12 \left( q_i + h_i - h_0 \right) \left( h_i - h_0 \right)^2 \left( h_i - h_1 + 6 \beta \right), \]  
\[ A_i = 6 \left( q_i + h_i - h_2 \right) \left( h_i + h_0 \right) \left( h_i - h_2 + 6 \beta \right) \]  
\[ A_i = -1 + 6 \left( q_i + h_i - h_2 \right) \left( h_i - h_2 + 6 \beta \right) \left( h_i - h_0 \right) - h_2 \]  
\[ A_i = \left( \frac{q_i}{2} + h_i \right) + \left( q_i + h_i - h_2 \right) \left( 6 \beta h_i \left( h_i - h_2 \right) - h_0 + 3h_2^2 \right) \]  
\[ A_i = \left( \frac{q_i}{2} + h_i \right) \]  
\[ \left( h_i - h_0 \right)^2 \left( h_i - h_2 + 6 \beta \right) \]  
\[ A_i = 6 \left( h_i^2 - h_2 - 2 \beta h_2 + \beta \right) + L_{14}, \]  
\[ A_i = \left( h_i - h_2 \right)^2 \left( h_i - h_2 + 6 \beta \right) \]  
\[ A_i = -\frac{q_i}{2} \left( 2h_i - 3h_0 \right) - 6h_0 \left( h_i^2 - h_2 - 2 \beta h_2 + \beta \right) - L_{10}. \]  
\[ L_{11} = \frac{-(n-1)c_i^3}{40}, \]  
\[ L_{12} = \frac{-(n-1)c_i^2 c_2}{8}, \]  
\[ L_{13} = 5L_{14} h_2 \left( h_2 + 4 \beta \right) + 4L_{14} h_2 \left( h_2 + 3 \beta \right), \]  
\[ L_{14} = 5L_{14} h_2 \left( h_2 - 4 \beta \right) + 4L_{14} h_2 \left( h_2 - 3 \beta \right). \]  

B. Solution for system of order \(1\) (the index should be 2):

Substituting the zeroth-order solution (51) and Eq. (45) and solving the resulting system along with the corresponding boundary conditions we obtain
\[ \psi_i = C_i \frac{y^3}{3!} + C_i \frac{y^2}{2!} + C_i y + L_{14} y + L_{14} y. \]  
where
\[ C_i = \frac{-12 q_i + L_{12} \left( h_i - h_2 \right)}{\left( h_i - h_1 \right)^2 \left( h_i - h_1 + 6 \beta \right)}, \]  
\[ C_i = \frac{6 q_i + L_{14}}{\left( h_i - h_2 \right)^2 \left( h_i - h_2 + 6 \beta \right)}, \]  
\[ C_i = \frac{6 q_i \left( h_i^2 - h_2 - 2 \beta h_2 + \beta \right) + L_{14}}{\left( h_i - h_2 \right)^2 \left( h_i - h_2 + 6 \beta \right)}, \]  
\[ C_i = -\frac{q_i}{2} \left( 2h_i - 3h_0 \right) - 6h_0 \left( h_i^2 - h_2 - 2 \beta h_2 + \beta \right) - L_{10}. \]  
\[ L_{11} = \frac{-(n-1)c_i^3}{40}, \]  
\[ L_{12} = \frac{-(n-1)c_i^2 c_2}{8}, \]  
\[ L_{13} = 5L_{14} h_2 \left( h_2 + 4 \beta \right) + 4L_{14} h_2 \left( h_2 + 3 \beta \right), \]  
\[ L_{14} = 5L_{14} h_2 \left( h_2 - 4 \beta \right) + 4L_{14} h_2 \left( h_2 - 3 \beta \right). \]
\[ L_{55} = \frac{L_{44} - L_{45}}{(h_1 - h_2 + 2\beta)}, \]

\[ L_{66} = \frac{1}{(h_1 - h_2)} \left[ L_{44} (h_1^3 - h_1^3) + L_{45} (h_1^3 - h_1^3) - L_{55} (h_1 - h_2) \right]. \]

\[ L_{47} = 6L_{45} (h_2 - h_2 - 2\beta) + 12L_{66}, \]

\[ L_{55} = L_{44} (h_1 - h_2) \left[ h_1 - h_2 + 6\beta \right] - \frac{1}{2} L_{45} (h_1 - h_2). \]

\[ L_{59} = \frac{1}{2} L_{47} (h_1 - h_2) \left[ h_2^2 - 2\beta h_2 \right] + L_{56} (h_2 - h_2) + L_{44} (h_1 - h_2) \left( h_1 - h_2 + 6\beta \right), \]

\[ L_{100} = \frac{1}{6} L_{44} (h_1 - h_2) + \frac{1}{2} L_{44} (h_1 - h_2) + \left( L_{101} + L_{102} \right) \left( h_1 - h_2 + 6\beta \right). \]

The axial pressure gradient is given by

\[ \frac{dp}{dx} = \frac{-12q_0 + L_{47} (h_1 - h_2)}{(h_1 - h_2) (h_1 - h_2 + 6\beta)} - \frac{648(n - 1) \left( q_0 + h_1 - h_2 \right) \left( h_1 - h_2 \right)^2}{(h_1 - h_2) (h_1 - h_2 + 6\beta)^3}. \]

Integrating Eq. (55) over the wavelength we get the pressure as

\[ \Delta P_{x1} = \frac{1}{d} \frac{dp}{dx}. \]

The perturbation series solution up to second order for stream function \( \psi \), velocity \( u \), pressure gradient \( dp/dx \) and pressure rise \( \Delta P_x \) may be summarized as

\[ \psi = A_1 \psi + A_2 \psi + A_3 \psi + A_4 \psi + We^2 \left( C_1 \psi + C_2 \psi + C_3 \psi + C_4 \psi + L_{11} y^2 + L_{22} y^3 \right). \]

\[ u = A_1 \psi + A_2 \psi + A_3 \psi + A_4 \psi + We^2 \left( C_1 \psi + C_2 \psi + C_3 \psi + C_4 \psi + 5L_{11} y^2 + 4L_{22} y^3 \right). \]

\[ \Delta P_x = \Delta P_{x0} + We^2 \Delta P_{x1}. \]

The non-dimensional shear stress of the channel reduces to

\[ \tau = \left[ \frac{1}{(h_1 - h_2) (h_1 - h_2 + 6\beta)} \right] + We^2 \left[ \frac{108(n - 1) \left( q_0 + h_1 - h_2 \right) \left( h_1 - h_2 - 2\beta \right)}{(h_1 - h_2) (h_1 - h_2 + 6\beta)^3} - \frac{6q_0 (1 - y) + L_{11} y + L_{15} y + 20L_{11} y^2 + 12L_{22} y^3}{(h_1 - h_2) (h_1 - h_2 + 6\beta)}. \]

By neglecting the terms of orders greater than \( O(We^2) \), the results given by Eqs. (57)–(61) are therefore expressed up to \( We^2 \). The frictional force, at \( y = \hat{h}_1 \) and \( y = \hat{h}_2 \) denoted by

\[ F_{11} = \int_0^1 \frac{-h_1^2 \left( \frac{dp}{dx} \right)}{dx}. \]

\[ F_{22} = \int_0^1 \frac{-h_2^2 \left( \frac{dp}{dx} \right)}{dx}. \]

### VI. RESULTS AND DISCUSSION:

In this section, the results are presented and discussed for different physical quantities of interest. The pressure rise is an important physical measure in the peristaltic mechanism. The perturbation method on Weissenberg number restricted us for choosing the parameters for Carreau fluid such that Weissenberg number is less than one. According to Bird et al. [16] the values of various parameters for Carreau fluid are: \( n = 0.398, 0.496. \) Fig. 2 is plotted for dimensionless pressure rise \( \Delta P_x \) versus the dimensionless flow rate \( \bar{Q} \) to the effects of partial slip \( \beta \), Weissenberg number \( We \), amplitude ratio \( \Phi \). The pumping regions are peristaltic pumping (\( \bar{Q} > 0, \Delta P_x > 0 \)), augment pumping (\( \bar{Q} < 0, \Delta P_x < 0 \)), retrograde pumping (\( \bar{Q} < 0, \Delta P_x < 0 \)), copumping (\( \bar{Q} > 0, \Delta P_x < 0 \)) and free pumping (\( \bar{Q} = 0, \Delta P_x = 0 \)). The variation of the pressure rise \( \Delta P_x \) with mean flux \( \bar{Q} \) is calculated from Eq. (60) and drawn in Fig. 2. at different parameters values. Figs. 2(a) and (2b) illustrate the pressure rise of the Carreau fluid (\( n = 0.398 \)) and Newtonian fluid (\( n = 1 \)) for various values of the partial slip parameter \( \beta \). It is shown in Fig. 2(a), that there is an inversely nonlinear relation between the pressure rise \( \Delta P_x \) and the time mean volume flow rate \( \bar{Q} \), i.e. the pressure rise decreases with increasing the
The velocity profiles for different values of volume flow rate, partial slip parameter $\beta$ and Weissenberg number are discussed in Fig. 3. It is observed from Fig. 3(a) that the velocity profiles increases with increase volume flow rate. Fig. 3(b) shows the influence of the partial slip parameter $\beta$ on the axial velocity, it is found that the magnitude of the axial velocity decreases in the center and increases nearer at the walls of the channel with increasing partial slip parameter $\beta$. Fig. 3(b) shows the effect of the Weissenberg number $We$ on the magnitudes of the velocity, it is observed that the profiles decrease with increasing Weissenberg number $We$. It is also observed in Fig. 3(d) that the velocity decreases from Carreau fluid ($n=0.398, 0.498$) to Newtonian fluid ($n=1$). Fig. 4 is plotted to see the effect of the parameters $Q$, $\beta$, and $We$ on the pressure gradient $dp/dx$. Figs. 4(a)-4(c) show that the pressure gradient $dp/dx$ decreases with increasing the volume flow rate, partial slip parameter $\beta$ and Weissenberg number $We$. Fig. 4(d) indicates that the pressure gradient increases from Carreau fluid ($n=0.398, 0.498$) to Newtonian fluid ($n=1$). The variation of the axial shear stress $\tau_{xy}$ with $y$ is calculated from Eq. (61) and is shown in Fig.5 for different physical parameters. In Figs. 5(a) and 5(c) we observe that the curves intersect at origin and the axial shear stress $\tau_{xy}$ increases with increasing the volume flow and Weissenberg number $We$ in the upper wall and an opposite behavior is observed in the lower wall of the channel. The relation between the shear stress $\tau_{xy}$ and $y$ at different values the partial slip parameter $\beta$ is depicted in Fig. 5 (b). We observe that the curves intersect at the origin and the shear stress $\tau_{xy}$ decreases with increasing the partial slip parameter $\beta$ above the origin while an opposite behavior is observed below the origin and no effect at the walls. It is observed from Fig. 5(d) that the shear stress $\tau_{xy}$ decreases from Carreau fluid ($n=0.398, 0.498$) to Newtonian fluid ($n=1$).

VII. CONCLUSION

In the present note, we have discussed the peristaltic motion of a Carreau fluid in an asymmetric channel with partial slip $\beta$. The two-dimensional governing equations have been modeled and then simplified using the long wave length approximation and then solved by using the perturbation technique. The results are discussed through graphs. We have concluded the following observations:

- The magnitude of the velocity field increases near the walls and decreases at the center of the channel with increasing the partial slip parameter $\beta$.
- The pressure gradient decreases with increasing the partial slip parameter $\beta$, Weissenberg number $We$ and the volume flow rate $Q$.
- In the peristaltic pumping region the pressure rise increases with increasing Weissenberg number $We$ and decreases as the partial slip parameter $\beta$ increases.
- The shear stress distribution increases in the upper wall and decreases in the lower wall with decreasing $\beta$ and decreasing Weissenberg $We$.
- The size of tapping bolus decreases with increasing the partial slip $\beta$ while it disappears at $\beta=0.06$.
- The size of the trapping bolus increases from Carreau fluid ($n=0.398$) to Newtonian fluid ($n=1$).

APPENDIX: EXPRESSIONS FOR WAVE SHAPES

The non-dimensional expressions for the five considered wave forms are given by the following equations:
I. Sinusoidal wave:
\[ h_1(x) = 1 + a \sin(x), \]  
\[ h_2(x) = -d - b \sin(x + \phi). \]  

II. Triangular wave:
\[ h_1(x) = 1 + a \left\{ \frac{8}{\pi} \sum_{m=1}^{\infty} \frac{(-1)^{m+1}}{(2m-1)^2} \sin((2m-1)x) \right\}, \]  
\[ h_2(x) = -d - b \left\{ \frac{8}{\pi} \sum_{m=1}^{\infty} \frac{(-1)^{m+1}}{(2m-1)^2} \sin((2m-1)x + \phi) \right\}. \]  

III. Square wave:
\[ h_1(x) = 1 + a \left\{ \frac{4}{\pi} \sum_{m=1}^{\infty} \frac{(-1)^{m+1}}{2m-1} \cos((2m-1)x) \right\}, \]  
\[ h_2(x) = -d - b \left\{ \frac{4}{\pi} \sum_{m=1}^{\infty} \frac{(-1)^{m+1}}{2m-1} \cos((2m-1)x + \phi) \right\}. \]  

IV. Trapezoidal wave:
\[ h_1(x) = 1 + a \left\{ \frac{32}{\pi^2} \sum_{m=1}^{\infty} \frac{\sin\pi(2m-1)}{(2m-1)^2} \sin((2m-1)x) \right\}, \]  
\[ h_2(x) = -d - b \left\{ \frac{32}{\pi^2} \sum_{m=1}^{\infty} \frac{\sin\pi(2m-1)}{(2m-1)^2} \sin((2m-1)x + \phi) \right\}. \]  

V. Sawtooth wave:
\[ h_1(x) = 1 + a \left\{ \frac{8}{\pi} \sum_{m=1}^{\infty} \frac{\sin(2m\pi x)}{m} \right\}, \]  
\[ h_2(x) = -d - b \left\{ \frac{8}{\pi} \sum_{m=1}^{\infty} \frac{\sin(2m\pi x)}{m} + \phi \right\}. \]

International Journal of Engineering Research & Technology

- Fast, Easy, Transparent Publication
- More than 50000 Satisfied Authors
- Free Hard Copies of Certificates & Paper

Publication of Paper: Immediately after Online Peer Review

Why publish in IJERT?
- Broad Scope: high standards
- Fully Open Access: high visibility, high impact
- High quality: rigorous online peer review
- International readership
- Retain copyright of your article
- No Space constraints (any no. of pages)
