India,

**Abstract-** These days concrete hollow blocks are very popular in the construction of various load bearing non-load bearing structures. In this paper, we discuss about the compressive strength of hollow blocks made in different mix proportions with different replacements. The main motive of this paper is to investigate the different properties of different hollow blocks made in different sizes, materials, proportions in the mix. In this study the result giving the difference in compressive strength with the replacement of fine and coarse-aggregate with waste materials like vermiculite, cement kiln dust, quarry dust etc.

## I. INTRODUCTION

The basic requirement of human being is shelter. In ancient time human starts living in caves below ground level, after that they started constructing walls from mud, they developed the techniques of burnt clay brick masonry for making the structure part of the shelter.

Now days, hollow concrete blocks are being very popular in construction. These blocks are being mostly used in the construction of multi- storied buildings, factories and residential buildings. These concrete hollow blocks are commonly used in compound walls because of cheapness. These concrete hollow blocks are more useful due to its lightweight and the most important feature is ease of ventilation. The concrete hollow blocks are made out of mixture of cement, sand and stone chips. It reduces cement in masonry work and reduced the cost of construction.

The hollow concrete blocks found out due to different advantages-

1. Sound control
2. Small dead load
3. Resistance to fire
4. Adequate strength
5. Superior thermal insulation
6. Economy
7. Highly durable
8. Environmentally Eco friendly
9. Reduction in mortar consumption
10. Fast and Easier construction system
11. Better Architectural features

The first Concrete block as a replacement for stone and wood in the building was used in the United States. The first concrete block house built up in 1837 on Staten Island in New York.

Harmon S. Palmer, designed first hollow concrete block in 1890. Palmer patented the design of hollow block in 1900 after 10 years of experimental research. Palmer's blocks were 8-inch(20.3cm)×10-inch(25.4cm)×30-inch(76.2cm) and they

were heavy in weight. These early hollow blocks were cast by hand and average output was about 10 blocks per hour. Now concrete blocks are manufacturing by automated process that can make up to 2000 blocks per hour.

The Compressive strength of masonry is one of the most important property in the design of masonry structure. This strength depends upon several factors such as unit strength, mortar strength, grouting, grout strength, geometry of the blocks, bedding mortar, and the type of bonding and bedding arrangements adopted. In extreme hot or cold climate countries these concrete blocks possessing low thermal conductivity and also serve as a thermal insulation material which minimize the energy consumption by minimizing the dependence on electricity for air conditioning or heating. In all countries, the different conventional materials are replacing to the concrete hollow blocks because most conventional materials cost is increasing. In the review study we found that hollow blocks of double- H shape gives more strength with semi-grouted masonry and low strength with fully grouted masonry.

## II. LITERATURE REVIEW

H. S. Sureshchandra, G. Sarangapani, and B. G. Naresh Kumar(2014)[1] find out the compressive strength of hollow blocks with partial and full replacement of sand by quarry dust. After replacement he found that 50% replacement of sand gave high strength and 100% replacement of sand gave low strength.

Ernesto S. Fortes, Guilherme A. Parsekian, and Fernando S. Fonseca, A.M.(2014)[2] studied the compressive strength of un-grouted, grouted masonry and masonry units. This research work indicate an increase in the compressive strength of the masonry with increasing compressive strength of the units.

Liang Huang, Lejia Liao, Libo Yan, S.M. and Hongwei Yi(2014)[3] studied the compressive strength of double H concrete block masonry prisms under uni-axial compression. He discussed the effects of mortar strength, grouting and grout strength effect on compressive strength of the prism. The test result shows that the compressive strength of H block prism decreased with an increase of grouting and the ultimate load of the prisms increased greatly.

K. S. Al-Jabri, A. W. Hago, R. Taha, A. S. Alnuaimi and A. H. Al-Saidy(2009)[4] makes the block with waste materials: vermiculite and polystyrene which were used as light weight aggregates and cement kiln dust (CKD) which was the partial replacement for cement. The result shows that the light weight concrete blocks manufactured from polystyrene had

low thermal conductivity than vermiculite and ordinary concrete blocks and the addition of up to 15% CKD as cement replacement gives a negligible effect on the strength. Denise S. Sanchez and Lisa R. Feldman(2014)[5] determined that calculated tensile resistance of the reinforcement was greater for bars that were in contact and furthermore is in sensitive to the magnitude of the transverse spacing provided in the case of noncontact lap splices.

Thaniya Kaosol (2010)[6] has made study on the reuse of concrete waste as crushed stone for hollow concrete masonry units. The main objective was to increase the value of the concrete waste, to make a sustainable and profitable disposal alternative for the concrete waste. Attempts were made to utilize the concrete waste as crushed stones in the concrete mix to make hollow concrete blocks. Various percentages of crushed stones have been tried the amount (i.e. 0%, 10%, 20%, 50% and 100%). From the results they found concrete waste can be used to produce hollow concrete block masonry units.

M.K. Maroliya(2012)[7] found that the crack patterns developed in the structural elements such as wall and the strength of wall constructed with hollow concrete block gives the less strength as compared to brick masonry but cost of construction is very less.

### III. MATERIALS

Finally, complete content and organizational editing before formatting. Please take note of the following items when proofreading spelling and grammar:

#### A. Cement

Cement is the cementing material used in concrete hollow blocks. We can use ordinary Portland cement for manufacturing of concrete hollow blocks to find high strength. The primary function of cement is to bind the fine and coarse aggregate particles together. Today cement find the excess use in all types of construction works where high strength is required.

#### B. Coarse and Fine aggregates

Mineral aggregates are normally divided into two types based on their particle size. Aggregate particles passing through the 4.75 mm Indian Standard sieve are known as fine aggregate and the particles retained on 4.75mm Indian Standard sieve are known as coarse aggregate. Natural sand is often used as fine aggregate in concrete mixture. Coarse aggregates are crushed stone chips made by the crushing stone boulders. Crushed stone particle sizes passing through the 4.75 mm sieve may also be used as fine aggregate. The maximum size of the coarse aggregate that may be used in concrete hollow blocks is 12.5 mm. It should be noted that the particle size must be up to 1/3 thickness of thinnest web of the hollow concrete blocks

#### C. Quarry dust

The quarry dust is the by-product of granite stones which can be produced when stones are broken down into the coarse aggregates of different sizes. This dust is the partial or full replacement of sand in the manufacturing of hollow concrete blocks.

#### D. Vermiculite

Vermiculite is a natural mineral that expands with the application of heat. It is a platy structure similar to that of mica and is found in many countries like South Africa, China, Brazil and several other countries. Vermiculite can expand up to 30 times of its original volume by exfoliation of thin plates when heated to temperatures of 650 to 1000°C.

#### E. Cement Kiln Dust (CKD)

Cement kiln dust is a byproduct of cement produced cement kiln by the dry process. It is generated during the calcining process in the kiln and also known as cement bypass dust. When the raw materials are heated, dust particles are produced in the kiln and then carried out with the exhaust gases at the upper end of the kiln. These gases are cooled and dust particles are collected by efficient dust collection system

### IV. QUALITY SPECIFICATION

As per the Indian Standard specification, a hollow block is defined as the block having one or more large holes of cavities which pass through the block and having solid material between 50 and 75 percent of the total volume of block calculated from the overall dimension. All the different types of cement concrete hollow and rigid bricks are covered by Bureau of Indian Standard (BIS) specification mentioned below:

#### F. Shape and size

Table 1 Size and weight of different hollow blocks

Ref No.	Description	Sizes in (cms)	Approx Weight in Kgs.
G4-1	Hollow Full	39 x 09 x 19	10.0
G4-2	Hollow Half	19 x 09 x 19	5.1
G5-1	Hollow Full	39 x 12.5 x 19	13.0
G5-2	Hollow Half	19 x 12.5 x 19	6.3
G6-1	Hollow Full	39 x 14 x 19	13.9
G6-2	Hollow Half	19 x 14 x 19	6.5
G6-3	Half Lintel	19 x 14 x 19	7.5
G8-1	Hollow Full	39 x 19 x 19	16.7
G8-2	Hollow Half	19 x 19 x 19	8.8
G8-3	Half Lintel	19 x 19 x 19	9.3
G8-8	Hollow Full	40 x 20 x 20	17.6
G9-1	Hollow Full	39 x 23 x 19	28.4
G10-1	Floor Slab	50x20x12.5	18.00

Fig. 1 Different shapes of hollow blocks

The maximum variation in the dimensions shall not be + 1.5 mm for height and breadth and + 300mm length. The size other than those mentioned above may also be used by mutual agreement between the purchaser and manufacturers/suppliers.

#### G. Cavities

The total width of the cavity in a block right angle to the face of the block as laid in wall (i.e. the bedding surface will be at right angles to the face of the block shall not exceed 65% of the total breadth of the block.

#### H. Shell Thickness

The shell thickness of blocks shall not be less than 40 mm.

#### I. Joints

The end of the blocks, which form the vertical joints, may be plain rectangle and grooved or double grooved.

#### J. Density

The block density hollow concrete block shall not be more than 1600 kg/cubic meter of gross volume.

#### K. Drying Shrinkage

The drying shrinkage of average of three blocks shall not exceed 0.004 per cent.

#### L. Moisture contents

The moisture content of the dried blocks on being immersed in water shall not exceed 0.03 %.

#### M. Water Absorption

The water absorption shall not exceed 10% by weight.

### V. COMPRESSIVE STRENGTH TEST

Each block was first dried, weighed, and placed between the platens of a compression testing machine. Soft wood plates were placed beneath and on the top of the block separating it from the platens of the machine. The load was applied in small increments until failure, and the failure load of the block was recorded. The stress at failure was calculated using the gross area of the block normal to the load

### VI. COMPARISON OF COMPRESSIVE STRENGTH

Below table is giving the comparison of compressive strength of the hollow blocks with the size of 20cm×20cm×20cm which are constructed by different mix proportions. Some replacement also take place like vermiculite with aggregate, CKD with cement and quarry dust with sand.

Table 2 Compressive strength with different mix proportions

Size (cm)	Mix Ratio	Material replacement	%	Strength (MPa)
20×20×40	1:2:0.5		0	28
20×20×40	1:2:0.5	Vermiculite with aggregate	30	14.1
20×20×40	1:2:0.5		0	10
20×20×40	1:2:0.5	CKD with cement	5	15
20×20×40	1:2:0.5	CKD with cement	10	10.6
20×20×40	1:3:6		0	2.25
20×20×40	1:4:0		0	1.9
40×20×20	1:3:6		0	3.69
40×20×20	1:3:6	Quarry Dust with sand	50	6.03
40×20×20	1:3:6	Quarry Dust with sand	100	5.78

### VII. CONCLUSION

The hollow concrete blocks of size 20×20×40 cm made with ratio 1:2:0.5 gives the best compressive strength 28 MPa the concrete hollow blocks of size 20×20×40 with vermiculite as partial replacement of aggregate gives just half compressive strength which is some time objectionable but not objectionable when use in non load bearing structures. The use of waste such as vermiculite, cement kiln dust and quarry dust makes the environment as pollution free and it reduces the cost of construction of hollow blocks which is beneficial for manufacturer and consumers. Many companies' faces more challenges in the disposal of these wastes, so the use of these waste reduces the disposal of the wastes and saving agricultural land from these wastes.
