Abstract— This paper is a study of a fingerprint recognition system based on minutiae based fingerprint algorithms used in various techniques. This line of track mainly involves extraction of minutiae points from the model fingerprint images and fingerprint matching based on the number of minutiae pairings among to fingerprints. This paper also provides the design method of fingerprint based student attendance with help of GSM. This system ignores the requirement for stationary materials and personnel for keeping of records. The main objective of this project is to develop an embedded system, which is used for security applications. The biometrics technology is rapidly progressing and offers attractive opportunities. In recent years, biometric authentication has grown in popularity as a means of personal identification in college administration systems. The prominent biometric methods that may be used for authentication include fingerprint, palmprint, and handprint, face recognition, speech recognition, dental and eye biometrics. In this paper, a microcontroller based prototype of attendance system using fingerprint sensor and face recognition module is implemented. The tracking module is used here to identify the location of the missing person.

Keywords—GSM, GPS, FINGER PRINT, LCD.

I. INTRODUCTION

The fingerprints are one of the main forms in biometric field which used to identify the individual and their uniqueness. Fingerprint authentication is one of popular authentication systems in the world. Due to their consistency and uniqueness it is used widely. There are several sources available for the collection and their established use [1]. In the past, magnetic card attendance system was widely used. But, this system has lot of bugs in it. The card may be lost or damaged. This fingerprint attendance system is highly secure and cannot be forged easily. In recent time, there has been high level of impersonation experienced on a daily basis in both private and public sectors, the ghost worker syndrome which has become a menace across all tiers of government, employers concerns over the levels of employee absence in their workforce and the difficulty in managing student attendance during lecture periods. Fingerprints are a form of biometric identification which is unique and does not change in one’s entire lifetime. This paper presents the attendance management system using fingerprint technology in a university environment. It consists of two processes namely; enrolment and authentication.

During enrolment, the fingerprint of the user is captured and its unique features extracted and stored in a database along with the users identity as a template for the subject. The unique features called minutiae points were exacted using the Crossing Number (CN) method which extracts the ridge endings and bifurcations from the skeleton image by examining the local neighborhoods of each ridge pixel using a 3x3 window [2]. During authentication, the fingerprint of the user is captured again and the extracted features compared with the template in the database to determine a match before attendance is made.

Attendance management system is one of the most advanced applications in biometric technology. It cannot be forged easily. With the integration and use of biometric technology getting simpler, many institutions are using down the biometric road to verify the time and attendance of their students and staffs. The system also contains a GMS Modem, which can be used to send the attendance information of the students automatically to their parents. The Embedded system using a small LCD user interface can be interfaced with the computer by using serial communication interface. The previous papers done were only the fingerprint based attendance system and a report generation [3].

The Fingerprint authentication has many advantages such as very high accuracy, the most economical biometric PC user authentication technique [4]. It is one of the safest biometric authentication methods widely used. It is very easy to use. Small storage space required for the biometric template, reducing the size of the database memory required and it is standardized. Biometrics technology can solve these problems and proposed fingerprint based attendance system would be ideal for implementation in universities for identification.

I. GENERAL BLOCK DIAGRAM

The fingerprints from the various users are acquired using the fingerprint module. For example we are taking the samples of
three or four fingerprints and they are enhanced using several enhancement techniques. After that we detect the edges along the image using the edge detection function. Here we use the pewit operator for the detecting the edges. We use minutiae matching algorithm for matching the finger print images. Instead of doing all these image processing works, we had used Fingerprint Module (R305) in this paper [5]. The circuit is made to be switched ON and all the initialization processes are done.

The “Initialization done” message has to be displayed in the screen. Up to that user should not keep any fingerprints for scanning. After that “Show the Finger” will be displayed on the screen. The fingerprint that has to be compared is already stored in the memory of fingerprint module. The fingerprint module is capable of storing about 100 images in the inbuilt memory. Now the fingerprints are kept for scanning with in a stipulated time period. Fingerprint module started to compare the results and it gives the hex codes to the microcontroller for further operations. The microcontroller starts to send the control to GSM based on the results from the finger print.

But the microcontroller has only one transmitter pin in it. We have to communicate both of the GSM and fingerprint module but not at a time. For that we are using Relay for switching between the GSM and fingerprint module. There are also commands for holding the fingerprints and for comparing it. The person whose fingerprint is matched and there will not be any SMS send to those persons. The persons whose fingerprints were not kept were sent only to those numbers. If the fingerprint of an unknown person is kept then the scanning will not take place. If unknown persons fingerprint is kept then the message “Not Identified” will be displayed. With the help of this the parents can be known about their arrival of the Students to the college or school [6].

A. Image Acquisition

The Fingerprint images from various users are taken using the module. The finger module itself has an internal memory which can store about 100 images in it. These images are used for the enhancement in next stages [7].

B. Image Enhancement

The image is enhanced using the techniques like Histogram Equalization [8]. It is nothing but the graph plot for number of pixels against the gray level. The overall contrast of the image is made uniform and image looks enhanced now the image is suitable for the extraction.

C. Edge Detection

They are many operators used for detecting the edges. The operators are Prewitt, Laplacian, Sobels, and Robertson Operators [9]. The Prewitt operator is one of the best edge detecting operator and we are implementing Prewitt operator in this paper. The edges have to be detected in order to match the input image with already saved image. There are two types of masking used here. They are

i) Horizontal masking

ii) Vertical masking

Edges are calculated by using difference between corresponding pixel intensities of an image. All the masks that are used for edge detection are also known as derivative masks. Because as we have stated many times before in this series of tutorials that image is also a signal so changes in a signal can only be calculated using differentiation.

II. FINGERPRINT RECOGNITION

The fingerprint recognition or fingerprint authentication refers to the automated method of verifying a match between two human fingerprints. Fingerprints are one of many forms of biometric used to identify individuals ad verify their identity. If unknown persons fingerprint is kept then the message “Not
After the extraction of edges, the points are marked in it. Those points which are detected after edge detection are known as miniature points. The miniature points that are extracted are compared with already stored image [10]. In order to find the matching process the correlation factor and the Euclidean distance has to be found out. Based on the tolerance value the matching results can be found out. The main purpose of the GSM in projects is to send and receive the messages.

D. Extraction of Miniature Points and Matching

After the extraction of edges, the points are marked in it. Those points which are detected after edge detection are known as miniature points. The miniature points that are extracted are compared with already stored image [10]. In order to find the matching process the correlation factor and the Euclidean distance has to be found out. Based on the tolerance value the matching results can be found out. The main purpose of the GSM in projects is to send and receive the messages.

Fingerprints are one of many forms of biometric used to identify individuals and verify their identity. If unknown persons fingerprint is kept then the message “Not Identified” will be displayed. With the help of this the parents can be known about their arrival of the Students to the college or school.
• Worldwide roaming
• Security
• Reasonable devices and facilities
• Extensive spectrums obtainable

After some time interval the details of the students who were not present were taken. Those persons details were taken and message of “NOT PRESENT” is sent to their respective parent’s mobile numbers. So, the parents may know about the student’s presence immediately. The Students cannot forget this system easily.

GPS, which stands for Global Positioning System, is a radio navigation system that allows land, sea, and airborne users to determine their exact location, velocity, and time 24 hours a day, in all weather conditions, anywhere in the world. The satellites transmit the exacta me the signals are sent. By subtracting the time the signal was transmitted from the time it was received, the GPS can tell how far it is from each satellite [13]. The camera used here is a PC web camera that captures the images of students for both database creation and test images [14]. The face recognition is the most important part of this system. It is an automatic method of identifying or verifying a person from a digital image or a video frame. It is done by comparing the extracted features from the captured image with the images that are previously stored in the predefined database [15].

V. PROPOSED SYSTEM

![Fig.9 Proposed system](image)

The system consists of fingerprint acquisition module and a GSM modem. Fingerprint acquisition module is used for capturing the fingerprint and pre-treatment [16]. GSM modem is used to send the attendance of the students to their parents in the form of SMS. The system hardware includes: fingerprint acquisition module, GSM modem, microcontroller, Camera (Face recognition), MAX-232, and LCD.

I. CONCLUSION

The fingerprint based attendance management system was implemented with Microsoft’s C# on the .NET framework and Microsoft’s Structured Query Language (SQL) Server2005 as the backend. The future work may consist of creating the database of students which contains the academic details of the students. We can send the academic details of the students periodically to the parent’s mobile along with the attendance report. So in near future we can use finger vein recognition in this attendance system which very unique compared to the fingerprint authentication. The authentication can also be made as more secure by using human odor for the Security purpose.
