"Flood Management of Jhelum Basin"

Abid Fayaz Al -Falah University

Abstract - Kashmir valley is highly prone to floods due to its geographical structure and location. Ever since the valley assumed its present form after draining out of the ancient karewa lake, the frequency of flood has been very high. Measures for flood mitigation were taken from 1950 onwards, a number of dams and barrages have been reportedly constructed. Floods continue to be a menace however mainly because of the huge quantity of silt being carried by the rivers emanating from Himalayas.

Key Words –Flood, Rainfall, Dredging, Tributries, Historical Floods, Flood Managment

1.INTRODUCTION

1.1 GENERAL

The state of Jammu and Kashmir covers an area of about 222236 sq.km extending from 320 17 N to 36058' N and from 730 26' E to 80030'E.The state is mountainously rising in several tiers from plains in the south to higher altitude valleys and peaks in north, enclosing some of the highest mountain peaks of the world. On the basis of climatic conditions state of Jammu and Kashmir is divided viz. Temperate Kashmir valley, Tropical Jammu province, Alpine Ladakh and Kargil regions .The Kashmir valley is surrounded by Himalayas which vary in their heights between 1000 feet to 1800 feet above mean sea level extending from 330 22' N to 340 43' N and 730 52' E to

750 42' E covering an area of about 15948 Sq.Km The Kashmir valley is bestowed with enormous and rich aquatic resources in the shape of lakes, rivers, streams, high altitude lakes, springs and low lying containing a total water spread of about 32765.3 hectares which is nearly 2% total land of Kashmir valley. The water bodies of Kashmir include the giant river Jhelum, India's largest fresh water lake Wular, world famous Dal lake, Mansbal lake, Nageen lake, springs like Achabal, Kokernag and Verinag, streams like Madhumati, Erin, Sindh, Bringi and high altitude lakes like Kishansar, Vishansar, Gangabal etc. The river Jhelum is called the life line entire of Kashmir valley from South to North and catering the requirements of 255 of population of the valley. It's the major water body of Kashmir valley. The river starting its journey from Verinag spring and travels first 241 kms in Kashmir, next 162 km in POK (PAKISTAN OCCUPIED KASHMIR) and remaining in 321 Pakistan, travelling a total distance of about 724 Km before merging with Chenab at Bunji in Pakistan.

1.2 Tributaries

The Jhelum basin has 19 tributaries and some of them drain from the slope of the Pir Panjal range and join the river on the left bank and some others flowing from Himalayan range and join the river on the right bank.

2 OBJECTIVE OF THE STUDY

To mitigate the flood

3. LITERATURE REVIEW

According to Nott (2006) the causes of flood can be divided into two physical (climate forces) and human influenced (urban development and vegetation clearing) categories. Most of the floods are due to natural forces world widely and in most of the cases it is due to prolonged rainfalls. Cutting trees has changed the patterns of floods which are due to the human impact. Flood cannot be considered as natural disaster until it damages the human lives or property.

Flooding is normally caused by natural weather events such as heavy rainfall and thunderstorms over a short period, prolonged rainfall or extensive rainfall. It can also be caused by high tide combined with stormy conditions. It is predicted that climate change will increase the risk of flooding in the UK and other parts of the world (Petak and Atkisson, 1982).

According to the study conducted by the International Flood Initiative (2003), floods are causing the most of the water related natural disasters which are not only damaging human and material assets but also the cultural and ecological resources. Ariyabandu and Wickramasighe (2005)observed that women are more affected than men due to their family responsibilities. Moreover women have more knowledge and skills to deal with such natural disasters but most of the time they are ignored in policy making.

Odunuga et al. (2012, p. 367) also established "that Flood occurs when there is overflow of urban drainages over the streets to extent that it cannot be absorbed by earth surface and consequently results to property damage, traffic obstruction and nuisance as well as health hazards".

According to Sinclair and Pegram (2003) stated that floods cannot be prevented but their effects can be minimized by introducing

advance warning systems. More over many poor people live near river banks because these are the only unoccupied areas available for poor populations. These people are at more risk not only due to their location but also due to lack of financial resources they own.

Flood may also result from overflowing of a great body of water over land and extreme hydrological events or an unusual presence of water on land to a depth which affects normal activities (Olajuyigbe, 2012; and PointBlankNews.com). It also occurs as a result of combination of meteorological and hydrological extremes as well as activities of man on drainage basin (Adeaga, 2008). Floods often cause damage to homes and businesses if they are located in natural flood plains of rivers (Tinh and Hang, 2003).

Flood causes many socio-economic and political dimensions which further give birth to many complex problems. Some of the problems are displacement of people, infrastructure damages such as destruction of roads, crops and loss of cattle and livestock. These destructions delay the on-going development and political processes (Theron 2007).

4. METHODOLOGY

For the flood management of Jhelum basin, the whole work was first of all divided into two steps.

1. Flood Frequency analysis.

2. Flood Management

4.1 Flood Frequency Analysis

For the flood frequency analysis the 50years discharge data was collected from planning and designing sub division of irrigation and flood control department and data was analysed for 50, 100,1000 years return period by GUMBEL distribution method in Microsoft excel, as follows.

4.2 Gumbel's Distribution

Gumbel's probability distribution a widely used method has been used for analysis of 40 years data collected at three gauge stations of rive Jhelum situated at SANGAM, RAMMUNSHI BAGH & ASHAM.

4.2.1 Sangam Gauge Station of River Jhelum

5. FLOOD MANAGMENT

5.1 Measures For Flood Management

5.1.1 Increasing the carrying capacity of existing flood mitigation infrastructure

- 1. River Jhelum treatment (dredging, resectioning etc).
 - Optimum functioning of the Flood Channels
 - 1. Flood Spill Channel (FSC) to 25000 Cusec/39000 cusec)
 - 2. Kutte Kull
 - 3. Sonar Kull
- 3. Wetland conservation

5.1.2 Dredging

It has been seen that velocity of the water in the Jhelum River is quite less due to very low bed grade and lot of sediment load gets deposited on the bed with the result there is a lot of reduction in the carrying capacity of the basin at different parts. So, the carrying capacity of these areas can be improved with dredgers.

- a. The outflow channels in the line of wullar intake need to be dredged to create laminar flow to the lake.
- b. The dredging of the river Jhelum must start from the tail end on the down-stream side of the river to avoid back flow and the dredging on the upstream side be taken up next, to avoid heavy flood

2.

discharge from the upstream side resulting in the overflow of embankments due to chocking through the city.

c. Fix time frame for each segment dredging controlled and monitored by the expert team based on primavera software. The total volumes for dredging should be monitored based on latest available equipment in the market.

5.2.2 Rise of Embankments

A levee or dyke may be defined as an earthen embankment extending generally parallel to the river channel and designed to protect the area behind it from overflow of flood waters.

Embankments are the oldest known forms of flood protection works and have been used extensively for this purpose. These serve to prevent inundation, when the stream spills over its natural section, and safeguard lands, villages and other properties against damages.

5.2.2.1 Embankment Classification

Manual, CW&PC, **Embankments**1960 stipulates that An embankment is designated as low, medium or major (according to its height above natural surface level (NSL).

- Low Embankment Height. < 10 ft. (3m.)
 Medium 10ft. (3m) Embankment <Height.> 30 ft. (9 m)
- 3 Major Height> 30 ft. (9 m Embankment)

5.2.3 Gabion Treatment

Visiting the site at Asham and the surrounding areas, a real bad situation of the site Hajan was found in which the side banks were completely washed out due to erosion of the material from the side walls and the extents of the erosion was so much that the whole side slope was washed out and the bank then converted into a vertical one.

On discussing about this issue with J.E"s at IFC, the reason behind this was found that the life of cohesiveness of the soil is over and now, the material of the banks has become loose and non-cohesive.

Discussing with J.E"s, we got to know that none of the erosion control measure work here, everything has been tried here from wooden piles to riveting but nothing as such worked. This place needs to be provided with the gabion treatment. And IFC"s team of engg. is even working on it.

5.2.4 Construction of flood water storage reservoirs in various tributary catchments of the River Jhelum (within the ambit of IWT 1960)

By the construction of storage reservoirs on the catchment of tributaries, a huge quantity of water can be arrested and besides a sediment load / silt, Carried by the tributaries shall be reduced to a great extent.

5.2.5 Additional Flood spill channel from Dorgipora (Pulwama) to Wullar Lake.

• Dogripora- wullar alternate channel to increase the capacity of the flood spill channel to 25000 cuses from the current 8000 cusecs would act as a major relief to the flood measures, this would be the least resistant path for flood mitigation and prevention

5.2.6 Flood Zoning (Hazard mapping of Kashmir)

- Areas under the risk of submergence.
- Proper city planning.

5.2.7 Life safety jackets and inflated rubber boats should be stocked by all the house-holds falling in the flood prone area. Young boys/girls need to be taught swimming to face any eventuality.

5.2.8Early Flood warning system

A flood forecasting system to be developed and installed that could provide 12-48hrs flood prediction in order to reduce the risk to people in future.

- Automatic Weather Stations (IMD)
- Doppler Radar (IMD)
- Automatic Water Level Recorders
 Proper announcement system
- Radio
- TV
- Social Media (Face book)
- Android App (Flood Alert)

5.2.9 Government must ensure availability of sufficient funds for executing the work in time-bound manner.
