Abstract

Handwritten character recognition is the ability of a computer to receive and interpret intelligible handwritten input from sources such as paper documents, photographs, touch-screens and other devices. Handwritten Devnagari Characters are more complex for recognition than corresponding English characters due to many possible variations in order, number, direction and shape of the constituent strokes. The main purpose of this paper is to introduce a method for segmenting first a text document of offline handwritten devnagari characters and then recognizing the same. The whole process of recognition includes two phases- segmentation of characters into line, word and characters and then recognition through feed-forward neural network.

Keywords—handwritten devnagari character recognition, Segmentation, line segmentation, word segmentation, character segmentation, lower modifier, upper modifier, Header line, Baseline, feed-forward neural network.

1. Introduction

Character recognition plays an important role in the modern world. It can solve more complex problems and make human’s job easier. An example is handwritten character recognition. Every individual has his own style of writing. Any individual having a very good knowledge of the script of a language can easily read some words written on a paper, though those are written in very bad manner, on the basis of his/her mental dictionary. Such words cannot be easily read by a machine as there may be various irregularities caused in expressing these words which are not easy to handle by a machine. Due to very strange styles of writing, a lot of difficulties are faced in machine recognition process. In recent years, a lot of research has been done in handwritten character recognition, but no work is done on the integration on segmentation and recognition of devnagari handwritten characters. Optical character recognition (OCR) is the mechanical or electronic translation of scanned images of handwritten, typewritten or printed text into machine-encoded text [1]. It is a process that converts words or characters, on a printed page into a digital image, and creates a digital file so that users can later search for that text and characters within that text. Handwritten character recognition is an important field of Optical Character Recognition. Here, in this paper, we will be considering the integration of segmentation and recognition using artificial neural networks.

The paper is organized as follows- The optical character recognition is introduced in section 2. Applications of OCR are discussed in section 2.1. Section 3 describes the Devnagari script. In section 4, the proposed system is given. The overall process is explained in section 5. The experimental results are discussed in section 6. Concluding remarks are given in Section 7.

2. Optical Character Recognition

Optical Character Recognition (OCR) translates the scanned printed or handwritten document images into a
Handwritten Character Recognition is an intelligent OCR capable of handling the complexity of writing, writing environment, materials, etc. Here is the Traditional OCR system structure [2, 6, 8]:

### 2.1. Applications of OCR

Following are the applications of OCR [3, 10].

1. Automatic text entry into the computer for desktop publication, library cataloguing, ledgering, etc.
2. Automatic reading for sorting of postal mail, bank cheques, postal code reading, commercial forms reading government records, manuscripts and their archival and other documents,
3. Document data compression: from document image to ASCII format,
4. Language processing such as indexing, spell checking, grammar checking, etc.,
5. Multi-media system design, etc.

### 3. Devnagari Script

Devnagari script is different from Roman script in several ways. This script has two-dimensional compositions of symbols: core characters in the middle strip, optional modifiers above and/or below core characters. Two characters may be in shadow of each other. While line segments (strokes) are the predominant features for English, most of the characters in Devnagari script are formed by curves, holes, and also strokes. In Devnagari language script, the concept of uppercase, the lower-case characters, is absent. But the alphabet itself contains more number of symbols than that of English. Marathi is an Indo-Aryan language spoken by about 71 million people, mainly the Marathi people of western and central India [4, 7]. It is the official language of the state of Maharashtra. Marathi is thought to be a descendent of Maharashtrian, one of the Prakrit languages which developed from Sanskrit.

We know that the Handwriting style varies from person to person. It has a large character set with curves and lines in the shape formation, which may be over lapping (touch) in a word. Touching characters can touch each other at different position because of individual writing styles vary greatly. Following are the various regions of a devnagari script [5, 21].

**Figure 2: Devnagari script structure**

Devanagari Script has 13 vowels (‘svar) and 36 consonants (‘Vyanjan’) and 10 numerals along with modifier symbols. All the individual characters are joined by a header line called “Shiro Rekha” which makes it difficult to isolate individual characters from the words. There are various vowel modifiers which add up to the confusion [4, 9]. Minor variations in similar characters can be there in the handwriting.

**Figure 3: Modifiers**
4. The Proposed System

So, the proposed system can be summarized as [3, 6, 11, 12, 13, 15, 18, 22].

- **Preprocessing**
  The total process of preprocessing of the image can be summarized as follows [4, 14] – Normalization, Binarization, Dilation, noise removal, thinning.

- **Line segmentation and word segmentation**
  It includes segmentation of lines based on the Bounding box formation. Detection of shirorekha has been done based on the line which contains maximum white pixels. For that purpose, first the joint points have been found out which is a new concept which never has been used. We removed the joint pixel which joins the shirorekha with the character. The lines with white pixels have been expanded, and the lines with maximum white pixels are detected as the shirorekha. Baseline has been also detected.

5. The Overall Process

In the proposed system, the recognition process of scanned text document image to the digitized image consists of the following steps [11, 17] - Preprocessing, Segmentation of lines, Segmentation of words, Segmentation of Characters, Recognition using neural network

- **Character segmentation**
For segmenting the characters, we have first identified the vertical bars. Then using the bounding boxes, the characters have been separated.

![Figure 11: Detection of vertical bars](image)

The Feed Forward neural network with one hidden layer has been used to recognize the segmented characters of devnagari script [16, 18, 19, 20]. In this work, we have taken 160 input nodes, that is, for 40 characters; we have taken 4 samples each. The hidden nodes are 40 and the output consists of 40 classes. The database used is as shown.

![Figure 13: Labelled characters](image)

6. Experimental Results

The method implemented here gives almost 100% results for the segmentation. The system is able to identify the Shirorekha, Baseline properly. It also does the line segmentation, word segmentation and character segmentation properly. The results of segmentation are promising. But it gives 60% results for the recognition of the handwritten devnagari text, as the devnagari text here which is taken as an input is handwritten. Also as the database is handwritten, the system is not able to recognize it 100%. From the experiments, we noticed that mainly the error occurred because of similar shaped characters and the connected characters.

7. Conclusion and Future Work

Development of handwritten Devnagari OCR is still a challenging task in Pattern recognition area. The integration of Segmentation and Handwritten Devnagari characters has never been done yet. Earlier, only integration of segmentation and recognition has been done only on the numerals, that too, is done on the English numerals.

There is a lot of difference between hand-printed and machine-printed. In hand-printed writing a lot of irregularities are committed by the writers. These irregularities drop the recognition rate of an OCR a lot.

A lot of work needs to be done for the recognition of handwritten devnagari characters. As a future work, we can work on recognition for getting more accurate results. Also, work needs to be done on the conjunct characters.
