Abstract

The kinetics of oxidation of L-Histidine by alkaline MnO₄⁻ have been investigated in the temperature range 298≤ T/K ≤318 at 0.004 ≤ [OH]/ mol dm⁻³ ≤ 0.03 and I= 0.5 mol dm⁻³. The observed rate of oxidation is first order with respect to L-Histidine and [OH]. The main product of oxidation is β-keto acid identified by ¹H NMR and FTIR. The ionic strength on the reaction rate has no significant effect. The effect of changing the dielectric constant of the medium on the rate indicates the reaction to be ion-dipole type. The electron transfer rate constant has been derived from the slow step of the mechanism of the reaction. The activation parameters with respect to slowest rate constants are computed. The moderate activation enthalpy and activation entropy favor the electron transfer reaction. An inner-sphere electron transfer mechanism is suggested. The proposed mechanism is consistent with the product, mechanistic and kinetic studies. Effect of micelles (SDS, CTAB) on such reaction have been studied. CTAB shows a marginal enhance rate where as SDS produces no change in the rate of the electron transfer reaction. Effect of solvent on such reaction have been investigated with protic (methanol, acetic acid) and aprotic (acetonitrile) solvent. Higher rate acceleration effect is observed in acetonitrile whereas low rate of acceleration is observed in methanol and acetic acid.

Keywords: Kinetics, oxidation, L-Histidine, Permanganate ion, micelle effect, solvent effect.

Introduction

Mostly L-amino acids are blood plasma ligands form stable complexes with various essential metals in vivo¹-³. These L-amino acids are used in many biological processes in human body like transamination, decarboxylation, metabolism, intracellular mechanism and operate specific transport systems of the plasma membrane. L-Histidine is one of the twenty amino acids which is present in many proteins. It plays a significant role in growth and repair of tissues, ulcers, hyperacidity, digestion, production of red and white blood cells, maintenance of myelin sheaths that protects nerve cells, particularly the auditory nerve is used to treat some form of hearing disability. Research on L-Histidine shows that its deficiency leads to rheumatoid arthritis, eczema (for babies), cataracts, stomach and duodenal ulcer. There is limited research on the oxidation of L-Histidine.

This paper presents detail investigation of interaction of L-Histidine with Manganese (VII) as permanganate ion. Potassium permanganate is a powerful oxidant in aqueous alkaline medium. It is interesting because manganese exhibits variable oxidation state from +2 to +7. The permanganate oxidation of large biological molecule such as nucleic acid [⁴], proteins [⁵], thymine [⁶], uracil [⁷] and several amino acids [⁸-¹⁰] have already been reported. This paper presents how manganese shows the change of various oxidation states during the course of the reaction. The product of the reaction have been isolated and characterised. Possible mechanism of the reaction has been suggested. Solvent and micellar effect on such reaction have been studied.

Experimental

Materials

All chemicals used were anaR grade. L-Histidine (SRL, extra pure) and potassium permanganate (BDH) were used as such without purification. Ionic strength was maintained with freshly prepared sodium perchlorate (Merck). Potassium permanganate was standardized with oxalic acid [¹¹]. Solvents were purified by reported method [¹²]. All solutions were prepared in freshly prepared double distilled water using an all glass distillation apparatus containing KMnO₄. SDS (Merck) and CTAB (Merck) micelles are used to study micellar effect on reaction mechanism. Fresh solutions of micelles are used for kinetic study.

Kinetic measurements

The kinetics of oxidation of L-Histidine was studied spectrophotometrically under pseudo-first order conditions with [L-Histidine]:[ KMnO₄]>10:1 at constant ionic strength (I = 0.5 mol dm⁻³). The L-Histidine was varied from 1 × 10⁻³ to 5 × 10⁻³ mol dm⁻³ and [OH⁻] was varied from 0.004 to 0.03 mol dm⁻³.

The Reaction Kinetics was followed by monitoring disappearance of Mn(VII) at λ max = 525 nm using conventional mixing technique with CECIL – 7200 (UK) UV – VIS spectrophotometer equipped with a thermostatic bath for temperature control with an accuracy of ± 0.1°C. The pseudo-first order rate constant (kobs) were evaluated from the slope of linear plots of ln (Ao – At) vs t(s) from the relationship.

\[ \ln (A_0 - A_t) = \ln (A_0 - A_e) - k_{obs}t \]
Where $A_0$, $A_t$, $A_{\infty}$ denote optical density of the reaction mixture at zero time, time $t$ and infinite time respectively. $A_t$ was measured after completion of the reaction. The correlation coefficients of plots used to determine $k_{obs}$ were found to be 0.99 in most of the cases. All calculations were made on a PC using least square programme.

**Stoichiometry and identification of Products**

Different sets of the reaction mixture containing different amount of reactants $[\text{MnO}_4^{-}] > [\text{L-Histidine}]$ at constant $[\text{OH}^-] = 0.03 \text{ mol dm}^{-3}$ and constant ionic strength $(I = 0.5 \text{ mol dm}^{-3})$ were allowed to react for 3hr in an inert atmosphere. The remaining $\text{MnO}_4^{-}$ was analyzed spectrophotometrically. The result showed that two moles of $\text{MnO}_4^{-}$ reacted with one mole of $\text{L-Histidine}$. From the above stoichiometric study it is concluded that the stoichiometry of the reaction is:

$$2\text{R-CH-COOH} + \text{MnO}_4^{-} + 2\text{OH}^- \rightarrow 2\text{R-C-COOH} + \text{MnO}_4^{2-} + \text{NH}_3 + \text{H}_2\text{O}$$

Where $R =$

![Reaction formula](image)

In order to get the reaction product 0.2 mol $\text{K MnO}_4$ and 0.02 mol of $\text{L-Histidine}$ were mixed in a container and $[\text{OH}^-]$ was kept at 0.03 mol dm$^{-3}$. The reaction mixture was allowed to stand about 3h at 303K for completion of the reaction. The metal ion in the solution was removed by ion-exchange method and after neutralization with dilute $\text{HClO}_4$ it was treated with saturated 2,4, dinitro phenylhydrazine. The yellow precipitate2,4, dinitrophenylhydrazone indicates the presence of Carbonyl group. One part of the solution was treated with Nessler’s reagent which confirmed the presence of $\text{NH}_3$. The solution after removal of metal ion was evaporated till it was reduced to one third of its original volume and kept overnight in refrigerator. The crystalline product formed was 60%. The product was identified by FT-IR as recorded in Perkin Elmer(UK) FTIR Spectrophotometer given in Fig. 1 as well as $^1\text{H}$ NMR spectra recorded in 400 MHz FT NMR Spectrophotometer given in Fig.2 [b].

FT-IR spectra of the product given in Fig.1 exhibits a broad peak at 3011 cm$^{-1}$ which is a combination of C-H stretching. N-H stretching of imidazole ring as well as O-H stretching of carboxylic acid. A sharp peak at 1738 cm$^{-1}$ corresponds to carbonyl stretching. The high value suggests intermolecular hydrogen bonding between C=O and O-H of carboxylic acid. Sharp peak at 1616cm$^{-1}$, 1487cm$^{-1}$, 1436cm$^{-1}$ corresponds to carboxylate group C-O stretching. The peaks of medium intensity from 1089cm$^{-1}$ to 1219cm$^{-1}$ also correspond to C-O stretching. The peak at 822cm$^{-1}$ corresponds to N-H outplane bending $^{[19]}$. All the above data predicts the product to be 2-imidazole pyruvic acid. The product was further confirmed by $^1\text{H}$ NMR data given in Fig.2 and Table 1. Sharp peak at 612.56ppm corresponds to OH group of carboxylic acid. The peak at $\delta$13.4 ppm corresponds to NH of imidazole. The peak at $\delta$6.86ppm , $\delta$6.76ppm corresponds to CH of carboxylic acid. The peak at $\delta$13.4 ppm corresponds to OH group of carboxylic acid. The peak at $\delta$12.56ppm corresponds to NH of imidazole. The peak at $\delta$16.86ppm , $\delta$6.76ppm corresponds to CH of imidazole $^{[20]}$. The CH$_2$ peak at $\delta$3.17ppm in the substrate shifted to $\delta$4.78ppm in the product is a clear indication of formation of C=O group. The NH$_2$ peak at $\delta$8.81 ppm in the substrate is absent in the product. The imidazole ring is not affected during oxidation is confirmed by the data given in Table1. The product was confirmed to be 2-imidazole pyruvic acid ,[3-(1-imidazole-2-yl)-2-oxopropanoic acid].

Results and Discussion

When L-Histidine was added to alkaline KMnO$_4$, the solution changes its colour from violet to blue then to green. The spectra of the green solution was identified as MnO$_4^{2-}$. It is probable that the blue colour originates from violet of permanganate and green colour from manganate excluding the accumulation of hypomanganate. It is unmistakable from UV-VIS spectral scan shown in Fig. 3[a] of the reaction mixture that the concentration of permanganate [Mn(VII)] ion decreases at 525 nm where as the concentration of manganate [Mn(VI)] increases at 608 nm and 460 nm during the reaction. After a long interval (after 5 hr) the peak at 525 nm completely vanished in Fig. 3[b] indicating the complete reduction of Mn(VII)

![UV-VIS Spectral scan for oxidation of L-Histidine by MnO-4 in aqueous alkaline medium](image)

[a] (1) [MnO-4] = $2 \times 10^{-4}$ mol dm$^{-3}$ (2) Immediately after mixing. MnO$_4^-$ with [L-Histidine] = $2 \times 10^{-3}$ mol dm$^{-3}$ curve (3-8), $\Delta t = 1$ min.

[b] Inset : Spectra of the above reaction mixture after 5 h.

The Kinetics of the redox reaction ($k_{\text{obs}}$) were followed at different concentration of oxidant, substrate and alkali at $\lambda_{\text{max}} = 525$ nm. The effect of alkali was studied by varying [OH$^-$] from (0.004 – 0.03) mol dm$^{-3}$ at constant concentration of L-Histidine and potassium permanganate and at constant ionic strength (I = 0.5 mol dm$^{-3}$) at different temperature 298-318 K. The plot of $k_{\text{obs}}$ versus [OH$^-$] is linear at different substrate concentration given in Fig. 4 indicates first order dependence with respect to alkali. The reaction is also first order with respect to L-Histidine concentration in Fig. 5 at different [OH$^-$] concentration. Increase in rate with increase in [OH$^-$] indicates the presence of the hydroxylated species of Mn (VII) as a reaction species which is shown in the mechanism of the reaction. The results suggest the formation of a complex between the amino acid and hydroxylated Mn(VII) complex. The formation of the complex was also proved by non zero intercept of the plot of $k_{\text{obs}}$ versus [Hist]$^{-1}$ displayed in Fig. 6.

![Figure 4. $k_{\text{obs}}$ versus [OH$^-$] at [L-Histidine] = $2 \times 10^{-4}$ mol dm$^{-3}$[1], $3 \times 10^{-4}$ mol dm$^{-3}$[2], $5 \times 10^{-3}$ mol dm$^{-3}$[3]](image)

![Figure 5. $k_{\text{obs}}$ versus [L-Histidine] at [OH$^-$] = 0.01 mol dm$^{-3}$[1], 0.02 mol dm$^{-3}$[2], 0.03 mol dm$^{-3}$[3]](image)
The effect of ionic strength was studied varying I = 0.01 to 0.05 mol dm$^{-3}$ (NaClO$_4$) keeping all other conditions remaining constant. The rate of the reaction remains almost unchanged with increasing (NaClO$_4$). This indicates that the rate of the reaction is independent of ionic strength showing the involvement of neutral species at the rate determining step.

Addition of acrylonitrile (6% v/V) to the reaction mixture in an inert atmosphere, produced cloudiness due to formation of poly acrylonitrile, indicating the formation of free radicals during the reaction. A similar solution of acrylonitrile when added to blank solution of KMnO$_4$ or L-Histidine did not produce any cloudiness.

The effect of relative permittivity (D) was studied by varying aqueous acetic acid 20% to 70% (Fig.8) keeping all other conditions constant. The observed rate constant (k$_{obs}$) was increased with decrease in dielectric constant of the medium. A plot of log k$_{obs}$ versus D$^{-1}$ is linear with positive slope indicating ion-dipolar interaction$^{[21]}$ in the rate determining step. Applying Born equation, Laidler and Eyring derived the equation$^{[22]}$.

$$\ln k = \ln k_0 + \frac{n D^2 e^2}{2DkT} \left( \frac{1}{r^*} - \frac{1}{r} \right)$$  \[1\]

Where $k_0$ is the rate constant in a medium of infinite dielectric constant and $r$ and $r^*$ refer to the radius of the reacting species and the activated complex respectively. It can be seen from the equation that the rate should be greater in medium of lower dielectric constant when $r^*>r$. The intra molecular hydrogen bonding that could stabilize the transition by increasing the size of activated complex by solvation is possible. It is likely that $r^*>r$ for L-Histidine thus explaining the experimental observation.

The energy of activation corresponding to the rate of the slowest step was evaluated from the plot of log (k/T) versus T$^{-1}$. The moderate values of activation parameters $\Delta$$H^\ddagger$=25.71 ± 1.73 KJmol$^{-1}$ and $\Delta$$S^\ddagger$ = 202.58 ±5.64 KJ mol$^{-1}$ favour outer sphere electron transfer processes. The $\Delta$$H^\ddagger$ values were due to release of energy of solution change in the transition state. The negative value of $\Delta$$S^\ddagger$ indicate the loss of degree of freedom and formation of rigid transition state (complex C$_2$). The shifting of peak of the reaction mixture shown in Fig. 3a indicates the formation of weak bridged complex between amino acid and Mn(VII) in complex C$_2$ suggesting inner electron transfer mechanism.

**Mechanism of the reaction**

L-Histidine exists in following equilibria between various L-Histidine species A$^+$, B$^+$, C, D with their equilibrium constants$^{[23]}$. In alkaline medium D$^-$ is the predominant species.
The UV–VIS spectral scan in Fig. 3[a] shows the formation of a complex between MnO$_4^-$ and amino acid in which bathochromic shift of 30nm of MnO$_4^-$ from 315 nm to 345 nm and hyperchromicity at 430nm was observed. Such complex formation between substrate and oxidant was also observed in other studies$^{[24]}$. Based on the above experimental result the probable mechanism may be delineated as in scheme-I.

Scheme - I

$$\text{OH} + \text{MnO}_4^- \rightarrow K_1$$

$$\text{R} = \text{CH} - \text{COO}^- + \text{Mn} \text{ (VI)} \rightarrow \text{R} = \text{CH} - \text{COO}^- + \text{Mn} \text{ (V)}$$

$$\text{R} = \text{C} - \text{COO}^- + \text{H}_2\text{O} \rightarrow \text{R} = \text{C} - \text{COOH} + \text{NH}_3$$

$$2\text{Mn} \text{ (V)} \rightarrow \text{Mn} \text{ (VII)} + \text{Mn} \text{ (III)}$$

$$2\text{Mn} \text{ (III)} \rightarrow \text{Mn} \text{ (IV)} + \text{Mn} \text{ (II)}$$

$$\text{Mn} \text{ (V)} + \text{Mn} \text{ (IV)} \rightarrow \text{Mn} \text{ (VII)} + \text{Mn} \text{ (II)}$$

HMnO$_4^-$ (C$_1$) forms a complex (C$_2$) with amino acid. The complex decomposed to form amino acid radical which is further oxidized to amino acid which in presence of water yields keto acid and ammonia. The keto acid was identified by FTIR and $^1$H NMR as 2 imidazolpyruvic acid. It was supported by earlier report that the oxidation of amino acid by tetrachloro aurate$^{[23]}$ hydrazyl radical$^{[24]}$ produced β-keto.

Basing on the above mechanism, rate law can be derived as

$$\text{Rate} = k [C_2] = k [\text{Hist}] [C_1]$$

$$\text{Rate} = k K_2 [\text{Hist}] [\text{MnO}_4^-] [\text{OH}^-]$$

$$[\text{MnO}_4^-] = [\text{MnO}_4^-]_e + C_1 + C_2$$

$$= [\text{MnO}_4^-]_e + K_1 [\text{MnO}_4^-]_e [\text{OH}^-] + K_2 [\text{Hist}] [\text{MnO}_4^-][\text{OH}^-]$$

$$= [\text{MnO}_4^-]_e + K_1 [\text{MnO}_4^-]_e [\text{OH}^-] + K_2 [\text{Hist}] [\text{MnO}_4^-][\text{OH}^-]$$

$$[\text{MnO}_4^-]_e = \frac{[\text{MnO}_4^-]_e}{1 - K_1 [\text{OH}^-] + K_2 [\text{Hist}] [\text{OH}^-]}$$

Putting the value of (2) in equation (1)

$$\text{Rate} = \frac{k K_2 [\text{Hist}] [\text{MnO}_4^-]}{1 + x_1 [\text{OH}^-] + x_2 [\text{Hist}] [\text{OH}^-]}$$

$$\text{Rate} = \frac{k [\text{Hist}]}{1 + x_1 [\text{OH}^-] + x_2 [\text{Hist}] [\text{OH}^-]}$$

is plotted against at different concentration of [OH$^-$] (eqn.5).

A straight line is found with slope $\frac{1}{K_1}$ and intercept yields reciprocal of electron transfer rate constant (k). Again $\frac{1}{k_{obs}}$ is plotted against at different concentration of [L-Histidine] (eqn.4). The new intercepts are plotted against $\frac{1}{[\text{Hist}]}$ (eqn. 4). From slope and intercept $K_2$ is calculated. The value of k(electron transfer rate constant) & $K_2$ (formation constant of the complex) are computed at five different temperature 298-318K and tabulated in Table 3. Calculated $K_2$ value(eqn.5) at 298K is 8.41 which is comparable with the reported data 6.74 at 298K.$^{[22]}$

Micellar Effect

The kinetics of oxidation of L-Histidine with MnO$_4^-$ was carried out in presence of SDS varying [SDS]= 0.005 to 0.07 mol dm$^{-3}$ at 303K (Fig.7 ). The rate constant in presence of SDS is almost equivalent to rate constant in aqueous medium which indicates the reaction exclusively occur in aqueous-pseudo phase. The presence of Cationic surfactant CTAB enhanced the rate of oxidation reaction about three times that of the rate in aqueous medium. The rate acceleration in presence of CTAB is observed upto [CTAB] =0.005 mol dm$^{-3}$ and reaches a
limiting value in the range \([\text{CTAB}]=0.01 \text{ to } 0.07 \text{mol dm}^{-3}\). The acceleration in the observed rate may be due to higher local concentration of both reactants and micelle as compared to their stoichiometric concentration in aqueous phase. The limiting value at higher concentration may be due to bimolecular micellar surface reaction. Similar results have been observed in several micellar catalysed reactions\(^{25-29}\).

**Solvent effect**

Solvent is a vital component for carrying out any reaction in solution. Many physico chemical process including reaction kinetics have also been investigated in non-aqueous and mixed aqueous solvent mixture in the present study. The oxidation of L-Histidine by \(\text{MnO}_4^-\) in alkaline medium was carried out with dipolar protic cosolvents (methanol, acetic acid) and dipolar aprotic cosolvent (acetonitrile). The rate constant against the volume percentage of solvent are displayed in (fig.8) which clearly indicate the rate acceleration effect in mixed solvent media. The effect is small in methanol and acetic acid but more pronounced in acetonitrile. In methanol and acetic acid rate slowly increases up to 70% but in acetonitrile the effect is maximum up to 20% but from 20% to 70% there is gradual retardation. The differential behavior is partly due to the solvation stabilisation of protic cosolvents (methanol, acetic acid) through Hydrogen bonding which is not possible for aprotic solvent (acetonitrile). The rate acceleration effect is linear in methanol-water medium where in acetonitrile the curve is non-linear which indicate the influence of preferential solvation and solvent structural effect on rate of the reaction. At high acetonitrile concentration there is solvent structural perturbation which affect the energy barrier of the reaction as a result activation entropy increases hence rate decreases. It explains the retardation of rate at higher acetonitrile concentration.

**Conclusion**

In conclusion analysis of the results can supply information about the mode of action on reaction condition. The mechanistic pathways of Amino Acid Oxidation occur probably through an intermediate of Amino Acid Radical type which leads further to Keto Acid. The present study also give some importance in understanding natural ageing and Oxidative stress process mainly due to generation of free radicals in vivo. This experiment also provides method of synthesis of \(\alpha\)-keto acid from amino acid (L-Histidine).
