Abstract: Fiber reinforced composites are finding applications in automobile industries, civil industries, aerospace industries and chemical industries respectively and also in marine applications in recent years. The term hybrid composite refers to the materials which consist of more than two constituents which are at nano level. Basically one of these compounds are organic and inorganic in nature. Hybrid composite materials are different from any other composite materials which are at macroscopic level. Paints are the first most hybrid materials which are prepared from organic and inorganic components. The organic polymers, rubber is used as inorganic material.

In this project work an attempt has been made to develop a hybrid composite material using Jute and E-glass fiber with Epoxy as matrix for different orientations such as 30°, 45° and 90° is fabricated using the Hand-Lay up technique. Different mechanical properties such as tensile, bending and compression were studied by preparing the specimen according to ASTM D 638 standards.

The tribological behavior for the above said material has been assessed with a computerized pin-on disc wear machine by operating in dry condition and with varying loads, and constant speed, length and time has been done. It has been found that for 90° orientation the coefficient of friction is high compared to other two orientations also the material or weight loss was found to be less.

Keywords: Laminates, Hand lay-up technique, Mechanical Properties, E-Glass, Jute.

1.1 INTRODUCTION

The development of composite materials and their related design and manufacturing technologies is one of the most important advances in the history of materials. Composite material comprise of strong load carrying material (known as reinforcement) imbedded with weaker materials (known as matrix). The primary functions of the matrix are to transfer stresses between the reinforcing fibers/particles and to protect them from mechanical and/or environmental damage whereas the presence of fibers/particles in a composite improves its mechanical properties like tensile strength, flexural strength, impact strength, stiffness etc.

The composite material used in this research was manufactured using plain weave mat of E-glass fabrics of 0.3mm thickness as synthetic reinforcement. Jute fibers were used as natural reinforcement. The matrix material was Epoxy (Lapox L12) resin and hardener(K6) was supplied by Atul Ltd Valsad Gujarat India.

2 COMPOSITEMANUFACTURINGMETHOD.

There are many techniques available in industries for manufacturing of composites such as compression molding, vacuum molding, pultruding etc. The hand lay-up process of manufacturing is one of the simplest and easiest methods for manufacturing composites. A primary advantage of the hand lay-up technique is to fabricate very large, complex parts with reduced manufacturing times. All composite specimens were manufactured using hand lay-up process. The prepared material is shown in Figure 1.

2.1 Experimental Procedure and Apparatus.

All experimental tests were carried out at Composite technology park (CTP) Bangalore India.
2.1.1 Tensile Test

Tensile testing, also known as tension testing, is a fundamental materials science test in which a sample is subjected to a controlled tension until failure. The results from the test are commonly used to select a material for an application, for quality control, and to predict how a material will react under other types of forces.

Tensile tests were carried out on rectangular specimens of dimensions (150 × 20 × 6)mm at room temperature, by the method described in ASTM D638. Composite specimens were tested in Universal Testing machine and a tensile load has been applied until it has failed.

2.1.2 Flexural Test

Flexural strength, also known as modulus of rupture, bend strength, or fracture strength a mechanical parameter for brittle material, is defined as a materials ability to resist deformation under load. The transverse bending test is most frequently employed, in which a specimen having either a circular or rectangular cross-section is bent until fracture or yielding using a three point flexural test technique. The flexural strength represents the highest stress experienced within the material at its moment of rupture.

Flexural testing commonly known as three-point bending testing was also carried out in Universal testing machine as per ASTM D638.

2.1.3 Compression Test

Compressive strength is a key value for design of structures. Compressive strength is often measured on a universal testing machine; these range from very small table-top systems to ones with over 53 MN capacity. Measurements of compressive strength are affected by the specific test method and conditions of measurement.

Composite specimens of dimensions(80 × 10×6)mm were horizontally placed on two supports and load was applied at the centre. Compressive test is also performed in Universal testing machine as per ASTM D638 with additional ribs for the support.

3 RESULTS AND DISCUSSIONS

All experimental tests were repeated three times to generate the data.

3.2 Wear Test

The performance of prepared composites under dry sliding condition, wear tests were carried out in a pin-on-disc wear test rig[DUCOM]. The test rig is shown in fig8. Prior to testing the pins and disc surface were cleaned with acetone. All of the tests were performed on hybrid composite of various orientations with applied loads of 10,20 and 30N.

Table 4 shows the test parameters for varying load test.

Table 5 shows the weight loss of the material for different orientation

The following graphs show the variation of co-efficient friction for different loading and orientations.
Fig 12 shows the variations in wear, co-efficient of friction, frictional force for 45° orientation for 10N load.

Fig 13 shows the variations in wear, co-efficient of friction, frictional force for 45° orientation for 20N load.

Fig 14 shows the variations in wear, co-efficient of friction, frictional force for 45° orientation for 30N load.

Fig 15 shows the variations in wear, co-efficient of friction, frictional force for 30° orientation for 10N load.

Fig 16 shows the variations in wear, co-efficient of friction, frictional force for 30° orientation for 20N load.

Fig 17 shows the variations in wear, co-efficient of friction, frictional force for 30° orientation for 30N load.

4 CONCLUSION

The effect of jute fiber on mechanical properties of glass fiber reinforced polyester composite was studied and it showed that by incorporating the proper orientation the some of the mechanical properties of the hybrid composite can be increased.

The specimens fabricated at 90° orientation have better mechanical properties than the other two orientations. Also by analyzing the graphs from the wear tests conducted for varying load of 10N, 20N and 30N for different orientation of fiber we observe that for 45° orientation the co-efficient of friction is high compared to other two orientations also the material or weight loss was found to be less in case of 90° orientation.
