Abstract: A stock market is a public market for the trading of company stock. It is an organized set-up with a regulatory body and the members who trade in shares are registered with the stock market and regulatory body SEBI. Since stock market data are highly time-variant and are normally in a nonlinear pattern, predicting the future price of a stock is highly challenging. Prediction provides knowledgeable information regarding the current status of the stock price movement. Thus this can be utilized in decision making for customers in finalizing whether to buy or sell the particular shares of a given stock. Many researches have been carried out for predicting stock market price using various data mining techniques. This work aims at using of Artificial Neural Network techniques to predict the stock price of companies listed under National Stock Exchange (NSE). The past data of the selected stock will be used for building and training the models. The results from the model will be used for comparison with the real data to ascertain the accuracy of the model.

Keywords: Stock prediction, Neural Network, NSE, Multi Layer Perceptron (MLP), MATLAB

INTRODUCTION:

From the beginning of time it has been man’s common goal to make his life easier. The prevailing notion in society is that wealth brings comfort and luxury, so it is not surprising that there has been so much work done on ways to predict the markets. Various technical, fundamental, and statistical indicators have been proposed and used with varying results. However, not one technique or combination of techniques has been successful enough. With the development of neural networks, researchers and investors are hoping that the market mysteries can be unraveled. A stock market is a public market for the trading of company stock and derivatives at an agreed price; these are securities listed on a stock exchange as well as those only traded privately. It is an organized set-up with a regulatory body and the members who trade in shares are registered with the stock market and regulatory body SEBI. The stock market is also called the secondary market as it involves trading between two investors. Stock market gets investors together to buy and sell their shares. Share market sets prices according to supply and demand. Stocks that are in demand will increase their price, whereas as stocks that are being heavily sold will decrease their price. Companies that are permitted to be traded in this market place are called “listed companies”. Investors in stock market want to maximize their returns by buying or selling their investments at an appropriate time. Since stock market data are highly time-variant and are normally in a nonlinear pattern, predicting the future price of a stock is highly challenging. With the increase of economic globalization and evolution of information technology, analyzing stock market data for predicting the future of the stock has become increasingly challenging, important and rewarding. Prediction provides knowledgeable information regarding the current status of the stock price movement. Thus this can be utilized in decision making for customers in finalizing whether to buy or sell the particular shares of a given stock.

Artificial Neural Network (ANN): It is often just called a neural network, is a set of interconnected links that have weights associated with them. The concept of ANN was derived from biological neural networks. Neural networks open up a new foray into the field of making efficient and usable predictions in order to optimize profits. Artificial Neural Networks are being used in numerous areas, as it is an irrefutably effective tool that aids the scientific community in forecasting about probable outcomes. Any ANN can be thought of as a set of interconnected units broadly categorized into three layers. These three layers are the input layer, the hidden layer and the output layer. Inputs are fed into the input layer, and its weighted outputs are passed onto the hidden layer. The neurons in the hidden layer (hidden neurons) are essentially concealed from view. Using additional levels of hidden neurons provides increased flexibility and more accurate processing. However, the flexibility comes at the cost of extra complexity in the training algorithm. Having more hidden neurons than necessary is wasteful, as a less number of neurons would serve our purpose just fine. On the other hand, having less hidden neurons than required would cause reduced robustness of the system, and defeat its very purpose. An illustration of a neural network is shown in Figure 1.

MLP Neural Network: Multi Layer Perceptron (MLP) is a feedforward neural network with one or more layers between input and output layer. MLP maps sets of input
data onto a set of appropriate outputs. Feedforward means that data flows in one direction from input to output layer (forward). An MLP consists of multiple layers of nodes in a directed graph, with each layer fully connected to the next one. Except for the input nodes, each node is a neuron (or processing element) with a nonlinear activation function. This type of network is trained with the backpropagation learning algorithm. MLPs are widely used for pattern classification, recognition, prediction and approximation. Multi Layer Perceptron can solve problems which are not linearly separable. MLPs separate classes via Hyperplanes. MLPs use distributed learning. MLPs have one or more hidden layers.

PROPOSED METHODOLOGY:

- To study the current stock market trend and collect trend data.
- To build prediction model for the companies listed under NSE using multilayer perceptron (MLP) Neural Network technique.
- To compare the model with real data for its accuracy.
- The past three years’ data of the companies listed under NSE are used for building, training and testing the prediction model for MLP algorithms.

Step 1: Data collection - Past data of stock market are collected from various authorized sources. The data of companies listed under NSE, for the duration of 36 months (1-1-2011 to 1-1-2014) have been collected.

Step 2: Developing MLP neural network algorithm to predict future stock price. With Neural Network Toolbox MATLAB, MLP neural network is built and trained for different combinations of data and parameters as shown in below snapshots.
For different combinations of data and parameters, this performance curve varies. Training of the model stops either it reaches to mentioned number of epochs (shown in Fig. 3) or when Mean Squared Error (MSE) is almost never improving after certain epochs. The circle in the performance curve shows the best validation performance. Error curve shows how much accurate the network is. For the target input index, error curve shows how much the predicted value varies from the actual value. More the grouping of curve towards 0 (zero), better the network is. Sudden up/down movement in the curve means, predicted value varies significantly from the actual value for that particular input index. Here, actual value is compared with the redacted value. In the output curve as shown in Fig. 7, blue line shows actual value for that particular input index and red line shows predicted value.

RESULTS:
For different combinations of data and parameters, the different results and outputs are taken for all the companies that are listed under NSE. Performance analysis is the most important part. The numbers here are very deceptive and careful analysis of the same is important.

MSE: Mean Square Error is obtained by squaring the difference of obtained output and the actual output. The main drawback of MSE is that the value of MSE increases with the increase in the stock price. Eg: Assume that a neural network is able to predict the price with 90% accuracy. For stock like Idea cellular whose price is in the range of 150-200 the maximum possible MSE is 400. If the same network is used for Infosys whose price is in the range of 2000 - 3000 the maximum MSE is around 90,000. Hence MSE is a very deceptive number. It is used by the system for training the weights. MSE varies with stock price hence cannot be used for comparison. We need a number which can be compared, for this Normalized MSE is the solution. Normalized MSE is obtained by dividing MSE with the stock price. Correct Direction %: Let us assume that the actual closing price of the stock is 100 Rs even if the predicted price is 99.9999 Rs it is not accounted in the above percentage. Hence correct direction % should alone not be used for the analysis. It is used along with the normalized MSE for comparing neural networks. Standard Deviation is used for identifying the range for the accuracy.

of the network. It is used along with Correct Direction %. Thus, Normalized MSE along with Correct Direction % and SD are used for comparing performance of the system.

CONCLUSIONS

Stock market data are highly time-variant and are normally in a nonlinear pattern, predicting the future price of a stock is highly challenging. Prediction provides knowledgeable information regarding the current status of the stock price movement. In the literature review, different data mining techniques for stock market prediction are reviewed. It is noticed that Artificial Neural Network technique is very useful in predicting stock indices as well as stock price of particular company. Many different algorithms have been used with neural network. Feedforward MLP neural network technique is considered to predict the stock price of companies listed under LI15 index of NSE. From the result table is can be concluded that MLP neural network technique gives the satisfactory output with
